

## Solutions to Assignment 3

Corrected bit period in question 1 to  $\frac{1}{125 \times 10^6} = 8 \text{ ns}$ .

### Question 1

The 4B5B Idle symbol is '11111'. When encoded using MLT-3 this results in a transition every bit interval (every  $\frac{1}{125 \times 10^6} = 8 \text{ ns}$ ). The voltage levels are 0 and  $\pm 1 \text{ V}$ . The waveform is thus:

### Question 2

A channel excess bandwidth parameter ( $\alpha$ ) of 0.33 means that the total (maximum) bandwidth of the channel is  $1 + \alpha = 1.33$  times the minimum required for no ISI. The gain of the channel is zero ( $-\infty \text{ dB}$ ) at a frequency of 60 MHz and so this is the total channel bandwidth. The minimum bandwidth for no ISI is  $\frac{60}{1.33} = 45 \text{ MHz}$ . The minimum bandwidth is half of the symbol rate for which there would be no ISI so this symbol rate is  $2 \times 45 = 90 \text{ MHz}$ .

### Question 3

If a bit rate of 2 Mb/s is transmitted over a BSC there are 2 million channel uses per second. If the channel has a capacity of 1 Mb/s then the capacity is  $\frac{1 \times 10^6}{2 \times 10^6} = 0.5$  bits per channel usage. The equation for the capacity ( $C$ ) vs BER ( $p$ ) for the BSC is:

$$C = 1 - (-p \log_2 p - (1 - p) \log_2(1 - p))$$

There is no closed-form solution for  $p$  but we can find a numerical solution. You can re-write the equation as

$$1 - (-p \log_2 p - (1 - p) \log_2(1 - p)) - 0.5 = 0$$

and solve for the roots of the equation. From the shape of the curve we know there will be two solutions: one between 0 and 0.5 and one between 0.5 and 1). There are many ways to find the roots:

- Use a calculator. For example, on the Sharp EL-W516XBSL enter the equation in the display as a function of  $x$  and use Math->Solver to find the roots.
- Use a spreadsheet. You can enter the value of  $p$  in one cell, the equation in another and either iterate one value manually, compute the equation for a range of values or use the "solver" feature. For example, we can plot capacity vs  $p$  for  $p = 0.85$  to 0.97 to find one of the roots:

- Use a root-finding function in a numerical analysis program such as `fzero` from Matlab or Octave.
- Use a web site such as [Wolfram Alpha](https://www.wolframalpha.com) which provides an on-line front-end to Mathematica's numerical analysis features.

Screen captures from the last method are as follows:

Input:

$$1 - (-p \log_2(p) - (1 - p) \log_2(1 - p)) - 0.5 = 0$$

Solutions:

$$\begin{pmatrix} p = 0.110028 \\ p = 0.889972 \end{pmatrix}$$

Thus the capacity is 1 Mb/s when the BER is 0.11 or 0.89.

---

#### Question 4

---

To find the remainder we can write the polynomial  $x^6 + 1$  as 1000001 and  $x^2 + 1$  as 101 and do long polynomial division using the arithmetic rules for coefficients from GF(2):

$$\begin{array}{r}
 10101 \\
 \text{-----} \\
 101 \mid 1000001 \\
 \phantom{101} 101 \\
 \phantom{101} \text{---} \\
 \phantom{101} 010 \\
 \phantom{101} \text{---} \\
 \phantom{101} 100 \\
 \phantom{101} 101 \\
 \phantom{101} \text{---} \\
 \phantom{101} 010 \\
 \phantom{101} \text{---} \\
 \phantom{101} 101 \\
 \phantom{101} 101 \\
 \phantom{101} \text{---} \\
 \phantom{101} 00
 \end{array}$$

So the remainder is 0.

Note that this is not the CRC.

---

#### Question 5

---

For a 100 Mb/s Ethernet switch with 8 ports where packets are continuously being received on each port:

(a) if the destinations of the packets are equally divided among the 8 ports, then a total of 100 Mb/s

$(8 \times \frac{1}{8} \times 100 \text{ Mb/s})$  will be output on each port. The total throughput will thus be 800 Mb/s.

(b) if the destinations of the packets are all the same then only that one port will have any traffic flowing out of it and the throughput will be 100 Mb/s.
